

Quiz 1

DATA 412/612

Write a function named `column_check` in an R script. It takes a data frame 'df' with exactly two columns. Returns **FALSE** if either of the columns is not numeric (`is.numeric`). If both columns are numeric, it computes their maximum values and returns **1** if the maximum of the first column is greater than or equal to the maximum of the second column. Otherwise, it returns **Second Column**.
